IMPLEMENTATION OF A FUZZY INFERENCE SYSTEM

Aim:

To implement Fuzzy Inference System.

Scenario:

A company wants to automate **employee performance evaluation** based on two factors:

1. **Work Experience (Years)**
2. **Project Success Rate (%)**

Using **Fuzzy Logic**, we classify employee performance as **Poor, Average, or Excellent**, which helps determine bonuses or promotions.

The system follows these rules:

- **If experience is low AND success rate is low → Performance is Poor.**
- **If experience is medium OR success rate is medium → Performance is Average.**
- **If experience is high AND success rate is high → Performance is Excellent.**

Procedure:

1. Define Input Variables:

- Experience (0 to 20 years)
- Success Rate (0 to 100%)

2. Define Output Variable:

- Performance Score (0 to 100%)

3. Create Fuzzy Membership Functions for Experience, Success Rate, and Performance:

- Low, Medium, High (for input variables)
- Poor, Average, Excellent (for output variable)

4. Define Fuzzy Rules:

- IF experience is low AND success rate is low → THEN performance is poor.
- IF experience is medium OR success rate is medium → THEN performance is average.
- IF experience is high AND success rate is high → THEN performance is excellent.

5. **Build the Fuzzy Inference System (FIS)** using control rules.
6. **Provide Input Values:**
 - Example: Experience = 12 years, Success Rate = 70%
7. **Perform Fuzzy Computation** to determine the final performance score.
8. **Output the Performance Score** based on fuzzy logic inference.

Program:

```
import numpy as np
import skfuzzy as fuzz
from skfuzzy import control as ctrl

# Define fuzzy variables
experience = ctrl.Antecedent(np.arange(0, 21, 1), 'experience')
success_rate = ctrl.Antecedent(np.arange(0, 101, 1), 'success_rate')
performance = ctrl.Consequent(np.arange(0, 101, 1), 'performance')

# Define fuzzy membership functions
experience['low'] = fuzz.trimf(experience.universe, [0, 0, 10])
experience['medium'] = fuzz.trimf(experience.universe, [5, 10, 15])
experience['high'] = fuzz.trimf(experience.universe, [10, 20, 20])

success_rate['low'] = fuzz.trimf(success_rate.universe, [0, 0, 50])
success_rate['medium'] = fuzz.trimf(success_rate.universe, [25, 50, 75])
success_rate['high'] = fuzz.trimf(success_rate.universe, [50, 100, 100])

performance['poor'] = fuzz.trimf(performance.universe, [0, 0, 50])
performance['average'] = fuzz.trimf(performance.universe, [25, 50, 75])
performance['excellent'] = fuzz.trimf(performance.universe, [50, 100, 100])
```

```
# Define fuzzy rules
rule1 = ctrl.Rule(experience['low'] & success_rate['low'], performance['poor'])
rule2 = ctrl.Rule(experience['medium'] | success_rate['medium'], performance['average'])
rule3 = ctrl.Rule(experience['high'] & success_rate['high'], performance['excellent'])

# Create FIS control system
performance_ctrl = ctrl.ControlSystem([rule1, rule2, rule3])
performance_sim = ctrl.ControlSystemSimulation(performance_ctrl)

# Provide input values
performance_sim.input['experience'] = 12 # Example: 12 years of experience
performance_sim.input['success_rate'] = 70 # Example: 70% success rate

# Compute fuzzy inference
performance_sim.compute()

# Print the output
print(f'Predicted Performance Score: {performance_sim.output['performance']:.2f}')
```

Output

```
Predicted Performance Score: 67.85
```
